GEORGIA

Southern diphthong weakening

- Weakening of canonical /aɪ ɔɪ aʊ/ occurs in Southern speech (Thomas 2003)
- /aɪ/ weakening
 - Most prevalent
 - Triggering feature of the Southern Vowel Shift (SVS) (Labov, Ash & Boberg 2006)
- /ɔɪ/ weakening
 - Most prevalent amongst African Americans, and older European Americans in the South
 - For everyone before laterals (Thomas 2008)
- /aʊ/ weakening
 - Widespread in European American Southern English (Thomas 2008)

Transcription & Production

- Many studies have compared transcriptions by multiple speakers
 - Henderson (1938), Ladefoged (1960)
 - Buckeye Corpus vowels had 74% agreement. (Pitt et al. 2005)
 - Read RP had 83% agreement (Eisen 1993)
 - Transcriptions are affected by transcriber and speech variables (Cucchiarini 1993)
- Fewer have compared transcriptions to production data.
 - Kerswell & Wright (1990) conclude that reliability is not certain.
- Sometimes Linguistic Atlas transcriptions are questioned
 - Johnson (2010:28–29) flat out doubts some LANE transcriptions
 - Regarding the LOT-THOUGHT merger, Mouton (1968:464) says the LANE fieldworkers were “hopelessly and humanly incompetent”.

This Study

Research question

How does perception compare to production in southern speech in Linguistic Atlas data?

Hypothesis

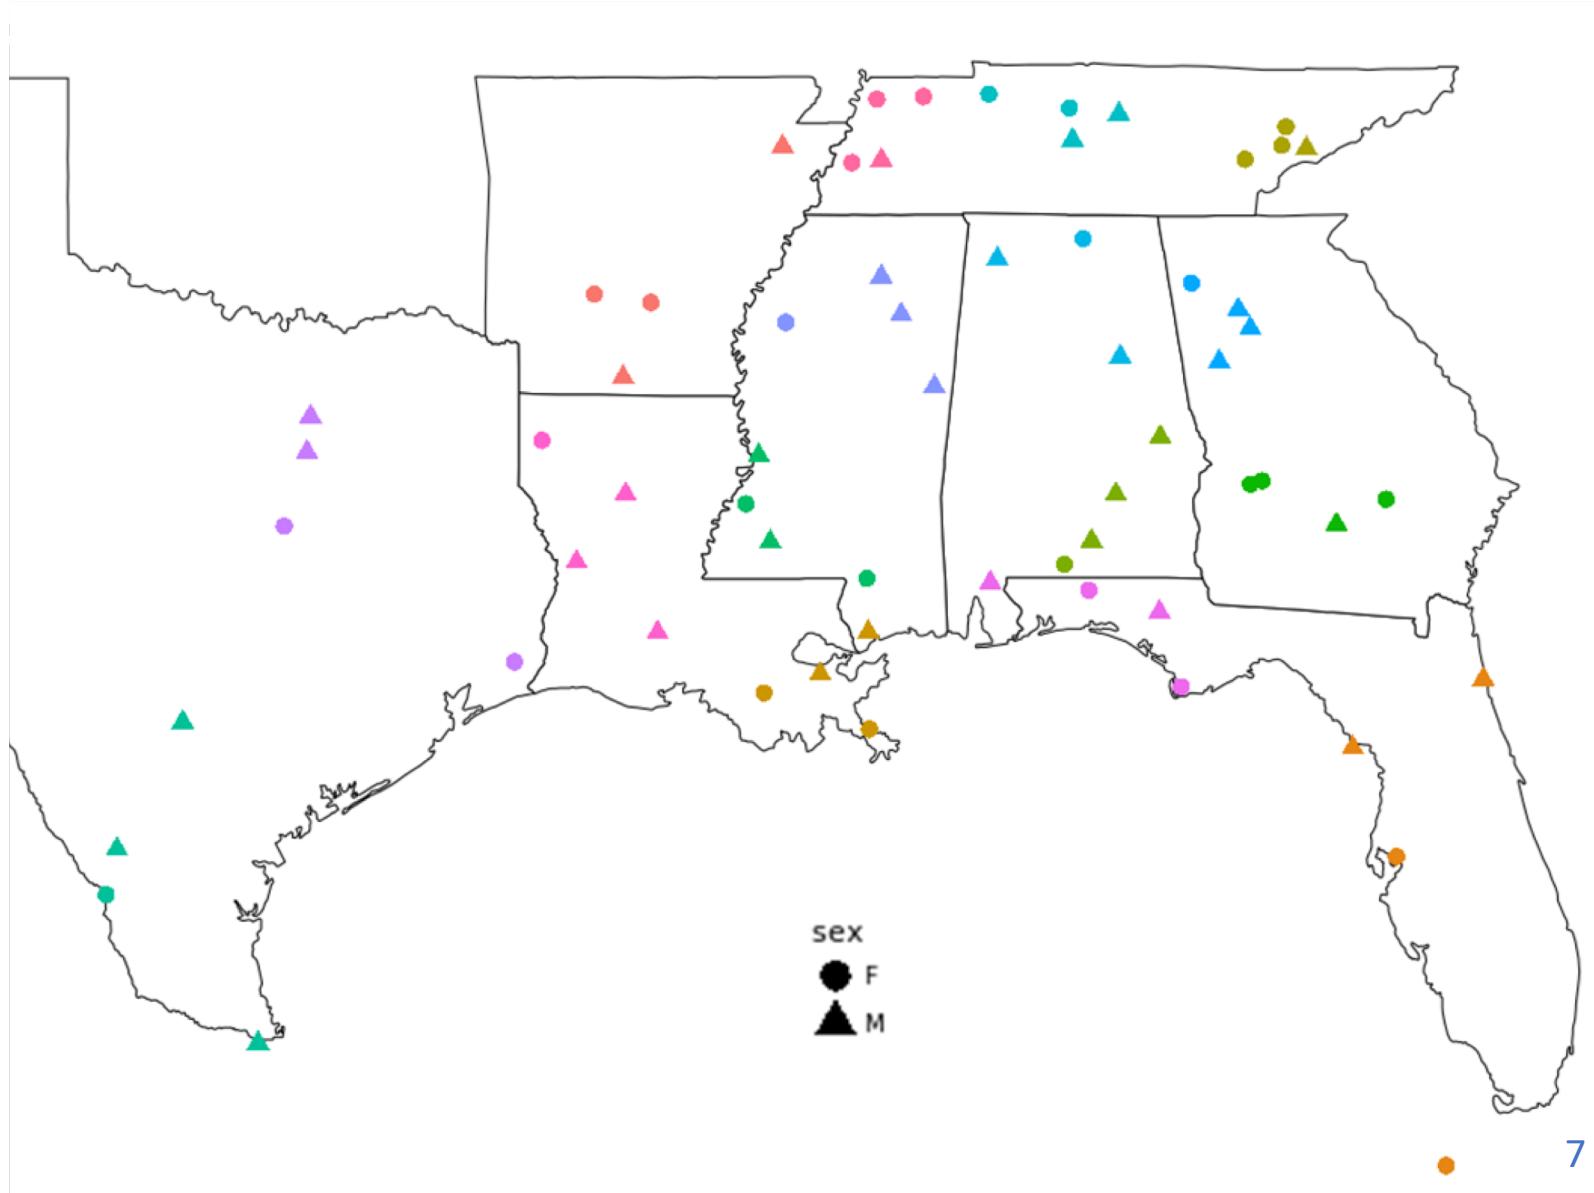

We expect impressionistic glide weakening to correlate with less dynamic vowels.

Methods

The Digital Archive of Southern Speech (DASS)

- Sociolinguistic audio corpus; subset of Linguistic Atlas of the Gulf States (Pedersen *et al.* 1986, Kretzschmar *et al.* 2013, Olsen *et al.* 2017)
- 64 speakers (30F)
 - Born 1886–1965 (μ = 61 years old)
 - Recorded 1970–1983
- 367 hours of audio (2.5–10 hours per interview; μ = 5.75 hours)
- 4 speakers for each of 16 geographical sectors
 - 1 African American (AA) speaker
 - 3 European American (EA) speaker “DASS Types”
 - Type I: Folk
 - Type II: Common
 - Type III: Cultured

Geographic distribution of DASS speakers

DASS Protocols

Methods

Compare:

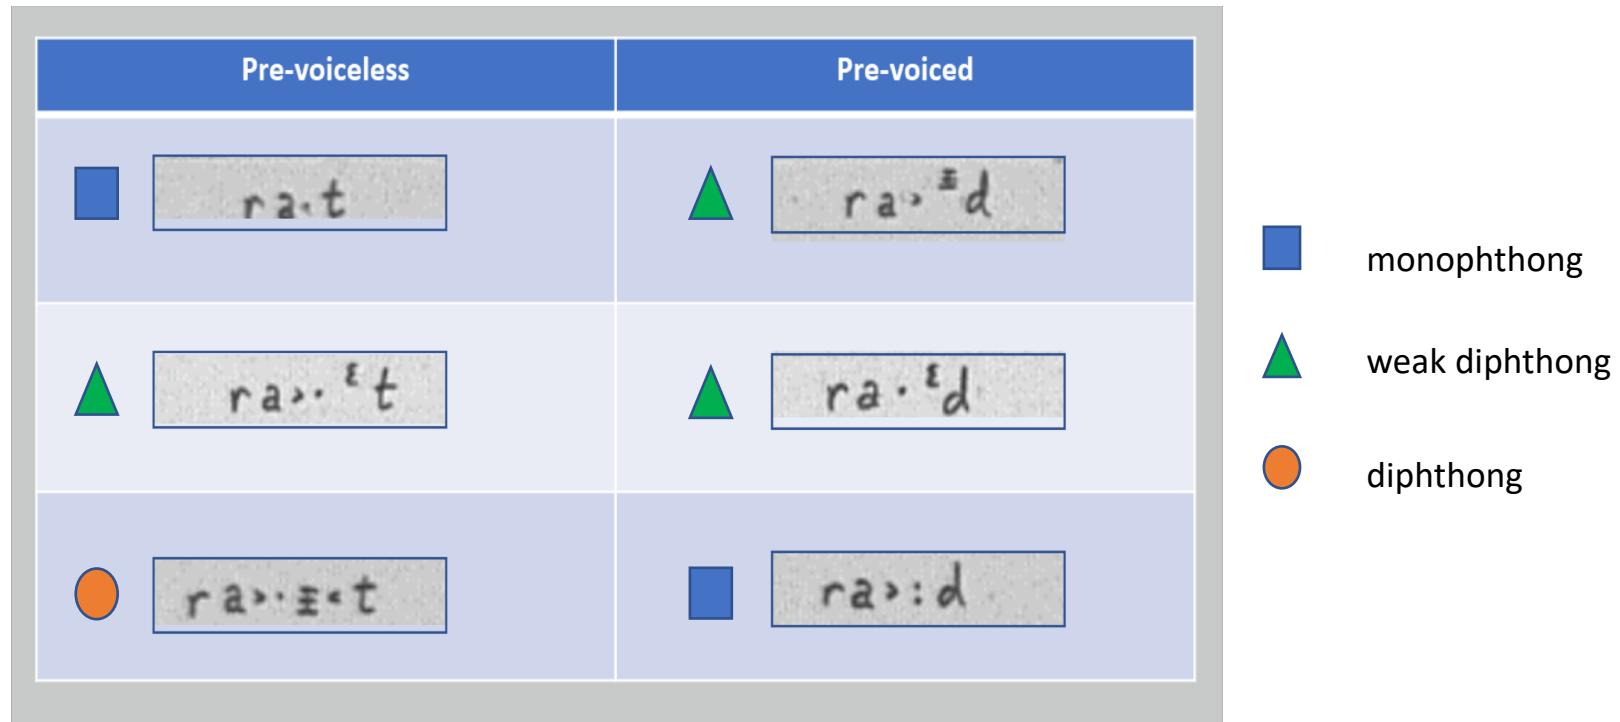

Impressionistic
transcriptions from Idiolect
Synopses.

63 speakers: 1,323 tokens

Acoustic data from the
same speakers.

107,854 tokens

Impressionistic/Perception Analysis

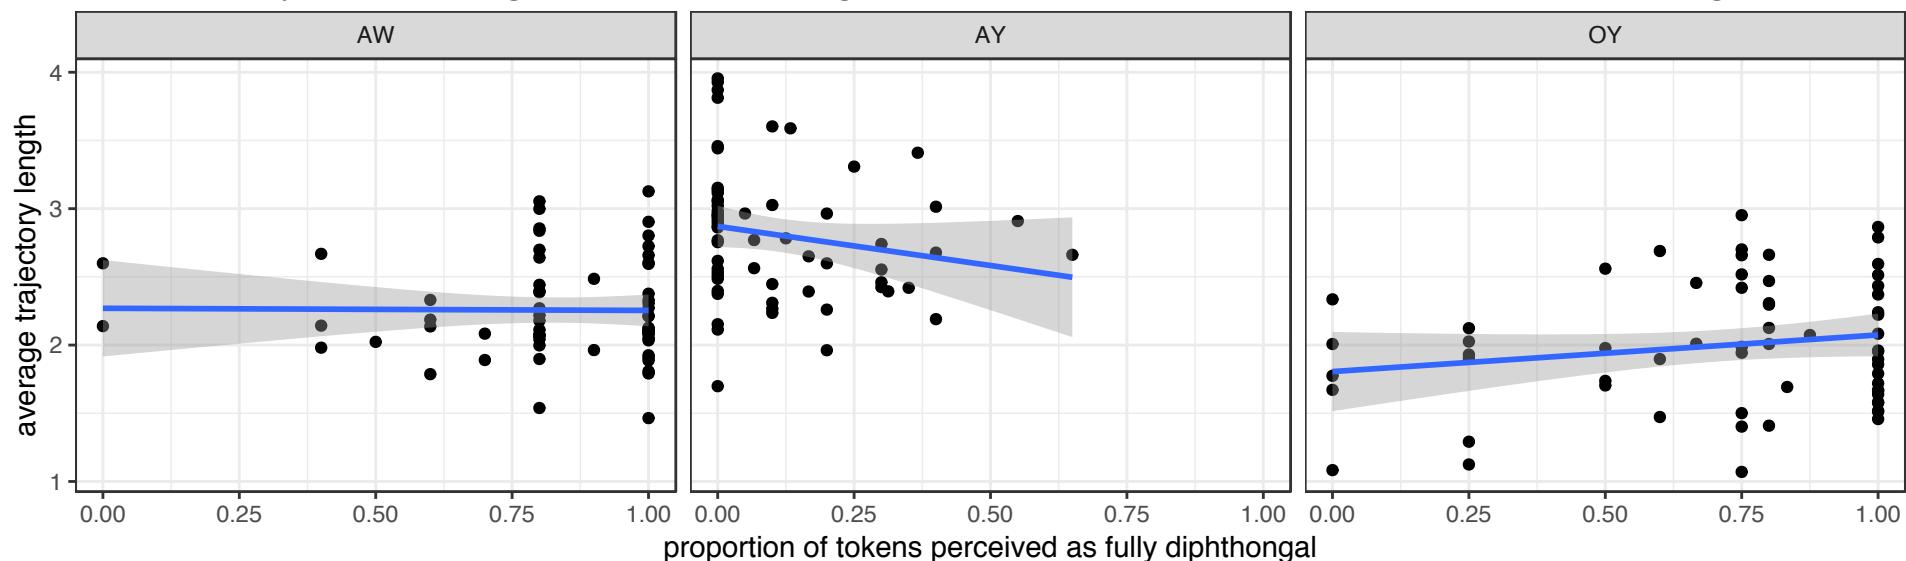

- Calculated percentage of monophthongized diphthongs for each speaker.

Acoustic/Production Analysis

- Data Processing
 - Fully transcribed DASS interviews force-aligned using DARLA (Reddy & Stanford 2015)
 - F1 and F2 extracted at five time points for stressed tokens of /aɪ ɔɪ aʊ/ (Rosenfelder et al. 2014)
- Trajectory length used to quantify diphthongization (Fox & Jacewicz 2009; Farrington *et al.* 2018)
 - Method
 - Composite measurement of F1 and F2 length between points in the vowel trajectory
 - 20%, 35%, 50%, 65%, 80%
 - Captures the amount of vowel movement across time
 - More dynamic vowels (i.e. diphthongs) have longer TL

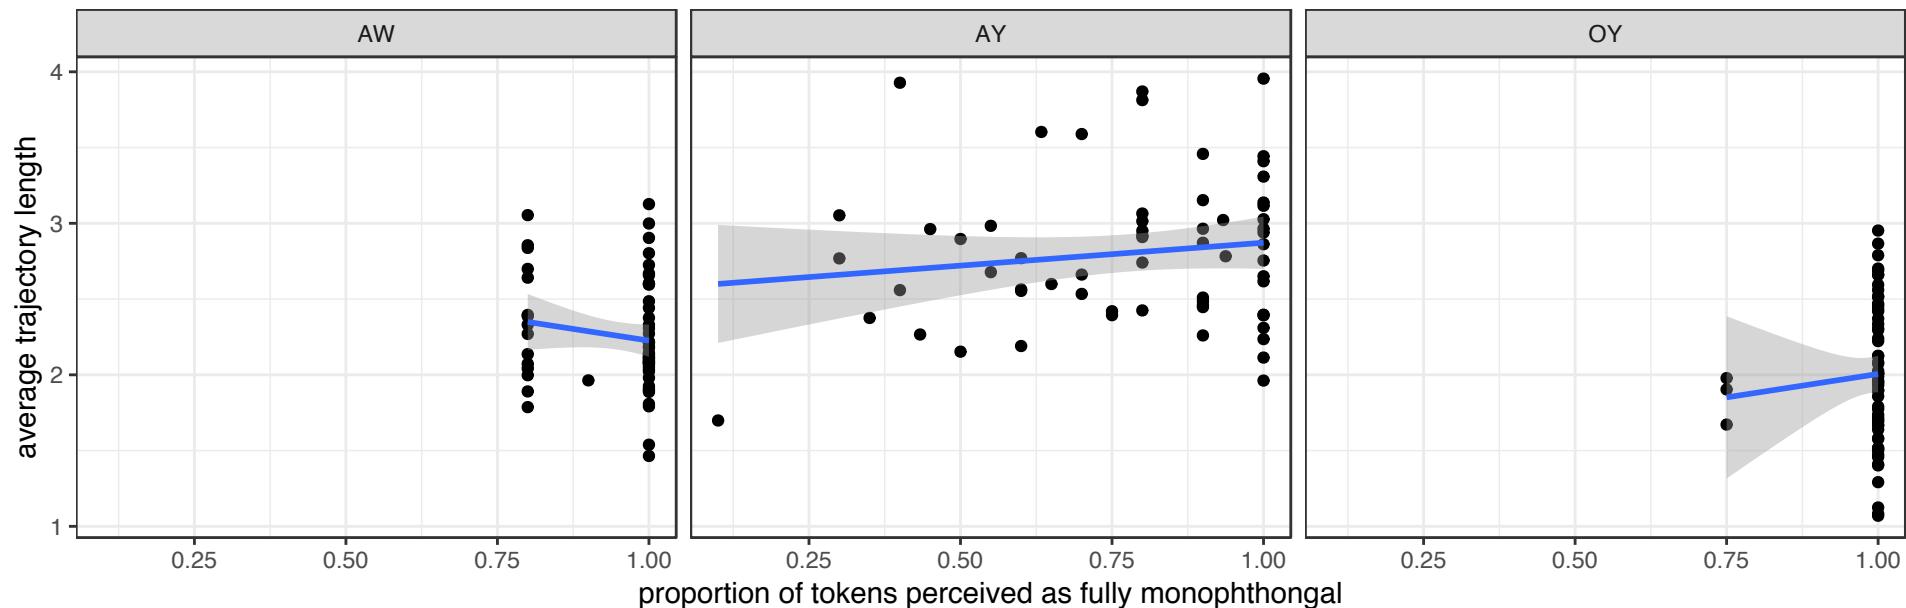

Results

Trajectory length by percentage of tokens transcribed as fully diphthongal

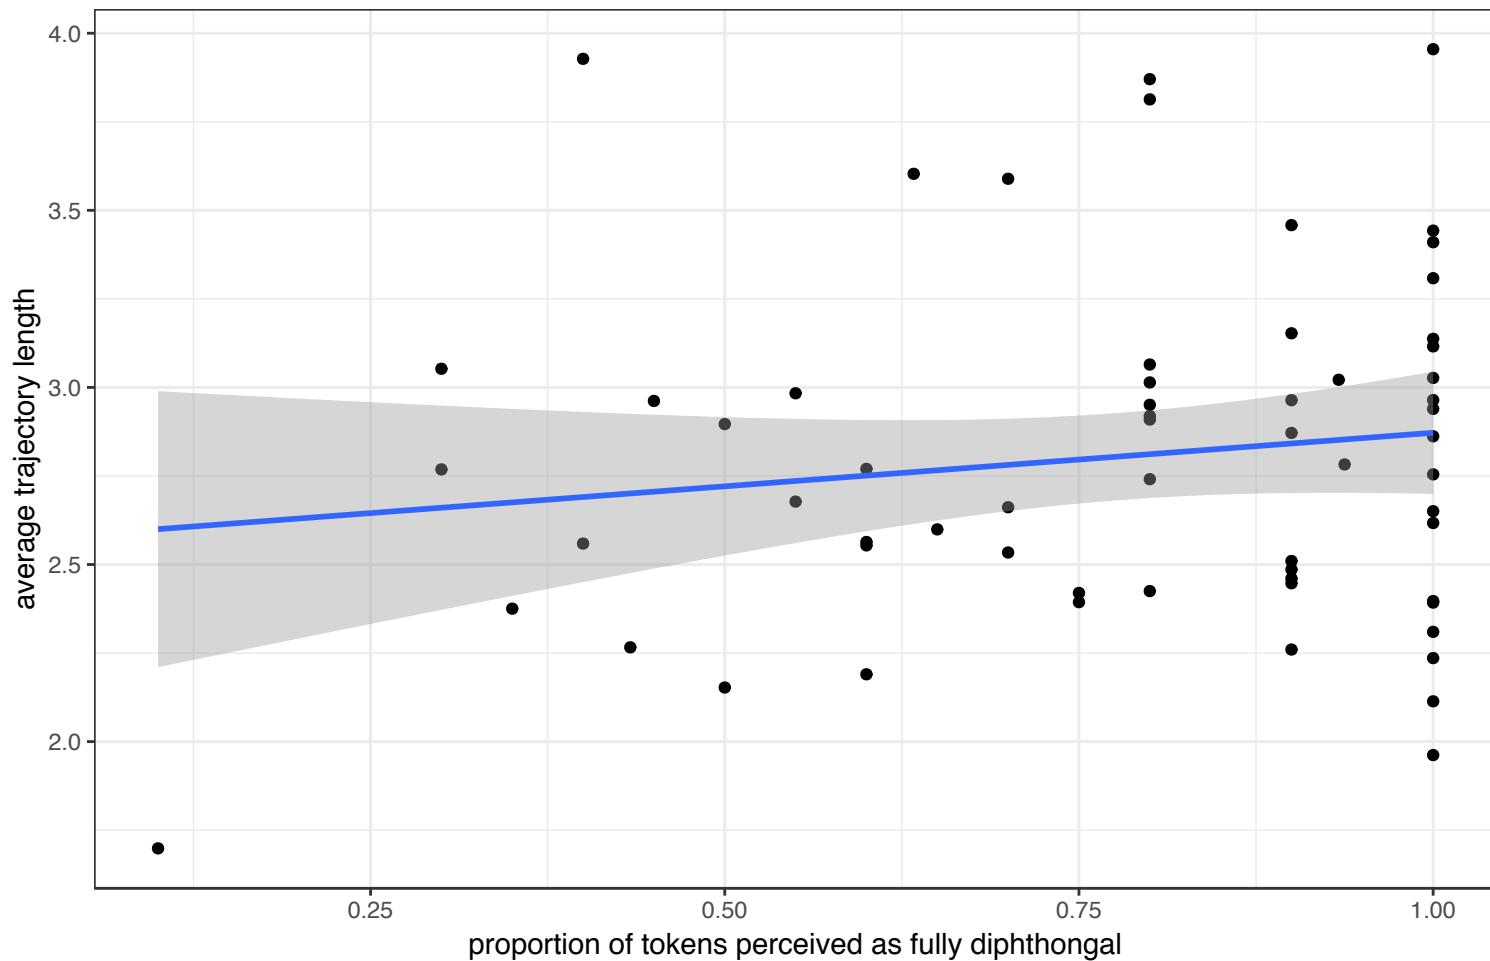

Monophthong = one vowel in transcription or superscripted offglide.
Diphthong = full vowel as offglide

Trajectory length by percentage of tokens transcribed as fully monophthongal

Monophthong = one vowel in transcription.
Diphthong = offglide as full vowel or superscript

Trajectory length by percentage of tokens transcribed as fully diphthongal AY only

Monophthong = one vowel in transcription or superscripted offglide.
Diphthong = full vowel as offglide

Mixed Modeling

Perceptual/Transcribed Data

- Dependent variable: Percentage of tokens transcribed as fully monophthongal
- Random effect: Speaker
- Fixed effects: Phonological environment, Default=voiceless Sex, Default=Female Ethnicity, Default=African American Year of birth

- Phonological environment significant
 - Rhotics transcribed as monophthongal more
- No social factors were significant

	β	<i>p</i>
(Intercept)	-0.087	0.962
Lateral	0.042	0.461
Nasal	0.023	0.688
Rhotic	0.247	< 0.001***
Voiced	-0.024	0.669

Mixed Modeling Production/Acoustic Data

- Same as previous, only trajectory length is dependent variable
- Phonological environment significant
 - L laterals (not rhotics) most weakened
- European Americans have significantly longer TL (i.e. more diphthongal production) than African Americans

	<i>B</i>	<i>p</i>
(Intercept)	-0.254	0.944
Lateral	-0.137	0.043*
Nasal	0.235	< 0.001***
Rhotic	0.193	0.011*
Voiced	0.149	0.027*
Voiceless	0.144	0.034*
European American	0.253	0.007**

Discussion and Conclusion

Discussion

- Acoustic and perceptual data also tell different stories.
 - Perceptual data suggest:
 - Social factors are not significant
 - Pre-rhotic glides are the most weakened
 - Production data suggest:
 - Ethnicity is significant
 - Pre-lateral glides are the most weakened
- As percentage of monophthongal perception goes up, Trajectory Length goes down, as expected, but the correlation is VERY weak.
- Trajectory Length is not necessarily reflective of impressionistic transcriptions of glides in DASS.

Conclusion

- The acoustic correlates to perception are not always straightforward.
- Production and perception must be considered in concert with one another.
- Future considerations:
 - Other potential acoustic measures of glide weakening, such as trajectory shape
 - A more fine-grained analysis of the Idiolect Synopsis transcriptions
 - Take into account the proposed second vowel of transcribed diphthongs, and weak diphthongs, as well as triphthongization
